RESPIRATOR SELECTION GUIDELINES

The following information provides only a brief summary of the respirator selection process, and is included in this appendix for educational purposes. For more information, follow the web links included at the end of this appendix or contact the EH&S Respiratory Protection Program Manager at 352-392-1591.

The first step in selecting the appropriate respirator is to identify the activity or process the individual will be engaged in. The concentration of the air-borne contaminant should be determined either through exposure assessments using air sampling methods or by making a reasonable estimate of the concentration encountered in the work area. These results are then compared to established “safe levels of exposure” using published exposure limits and guidelines.

Additional steps in the process include:
- Assessing the respirator’s assigned protection factors,
- The time the wearer will spend using the respirator,
- Researching existing standards for a chemical that may require a specific type of respiratory protection,
- The atmosphere the respirator will be used in (e.g. oxygen deficient) and
- The physical and filtering limitations of the respirator.

Respirators can be tight fitting or loose fitting as outlined below.

Respirators can be further categorized into two groups, air purifying and air supplied.

**Air Purifying Respirators**
These respirators remove air contaminants as they pass through the respirator filter. This respirator is to be used only where adequate oxygen (19.5 to 23.5 by volume) is present. Air purifying respirators are subdivided into the following types:

1. **Particulate Removing Respirators**: These respirators use a filtering device that physically filters out dusts, fibers, fumes and mists. These respirators may be single-use disposable filtering facepiece or dust mask respirators or respirators with replaceable filters. The current filter classification system is broken into two categories that designate the filter efficiency and the filters ability to work in environments containing oil particulate.

   **Classes of Filters**
   - There are nine classes of filters (three levels of efficiency, each with three categories of resistance to filter efficiency degradation)
   - Levels of filter efficiency are 95%, 99% and 99.97% (100%)
   - Categories of oil resistance are N (no oil), R (resistant to oil) and P (oil proof)
   - Filter designations are presented on the following table

<table>
<thead>
<tr>
<th>Filter Efficiency</th>
<th>N (Non-oil Environments)</th>
<th>R (Oil Resistant)</th>
<th>P (Oil Proof)</th>
</tr>

</tbody>
</table>
Types of Particulate Removing Respirators

Filtering Facepiece (Dust Mask)
A negative pressure particulate respirator with a filter as an integral part of the facepiece or with the entire facepiece composed of the filtering medium.

Powered Air-Purifying Respirator (PAPR)
An air-purifying respirator that uses a blower to force the ambient air through the air-purifying elements to the inlet covering.

Respiratory Protection for Tuberculosis and Other Infectious Diseases
Current CDC guidelines allow the use of all nine classes of loose fitting facepiece respirators. The N95 filtering facepiece is most commonly used. PAPR’s used for protection against infectious diseases must be equipped with HEPA filters. Respirator users should check the CDC website for any updates or changes to respirator use guidelines for infectious disease control.
NOTE: Surgical masks are not considered respirators and do not provide adequate protection from air contaminants. They are never to be used in place of an air-purifying respirator.

2. Gas and Vapor Removing Respirators: These respirators remove specific individual contaminants or a combination of contaminants by absorption, adsorption or by chemical reaction. Gas masks and chemical cartridge respirators are examples in this group. Combination respirators that remove both particulate and gas/vapor are available. The gas/vapor cartridges are typically identified by color coding. Typical color codes are presented on the following chart.

<table>
<thead>
<tr>
<th>Contaminant</th>
<th>Cartridge Color Code</th>
</tr>

<tr>
<td>Ammonia Gas</td>
<td>Green</td>
</tr>
<tr>
<td>Acid Gas and Organic Vapor</td>
<td>Yellow</td>
</tr>
<tr>
<td>HEPA or P100</td>
<td>Magenta (Purple)</td>
</tr>
</tbody>
</table>

All filters, cartridges and canisters used in the workplace must be labeled and color coded with the NIOSH approval label.

This label must not be removed and must remain legible.

NOTE: Where eye irritation is possible, a full facepiece respirator is required.

**Air Supplied Respirators**

These respirators provide breathing air independent of the environment. Such respirators are to be used when the contaminant has insufficient odor, taste or irritating warning properties or when the contaminant is of such high concentration or toxicity that an air-purifying respirator is not adequate. The most common type of air supplied respirator is the self contained breathing apparatus (SCBA). While this type of unit offers the greatest degree of protection, it is also the most complex.

Training and practice in its use and maintenance is essential and it is to be used only in emergency situations.
In addition, all work locations where there are atmospheres that are categorized as Immediately Dangerous to Life or Health (IDLH) require the use of a full facepiece, positive pressure demand SCBA certified by NIOSH for a minimum service life of thirty minutes or a combination full facepiece pressure demand supplied air respirator (SAR) with an auxiliary self contained air supply. All oxygen deficient atmospheres (<19.5% \(O_2\) by volume) shall be considered IDLH.
